

Part II

Chapter 7: The Immune Response

- Document 1: Non-specific Immune Response
- Document 2: Specific Immune Response
- Document 3: Induction of the Specific Immune Response
- Document 4: Role of TH in the Specific Immune Response
- Document 5: Specific Humoral Immune Response
- Document 6: Specific Cell-Mediated Immune Response
- Document 7: Immunological Memory
- Document 8: Diagnostic Applications of Antibody Properties
- Selected Exercises of Official Exams

Document 1

Non-specific Immune Response

- **Immune response:** is the reaction done by the immune system against a non-self.
 - It may be specific or non-specific.
- **There are three lines of defense in the body:**
 - 1- **Natural barriers:** First line of defense in the body.
 - 2- **Non-specific immune response:** 2nd line of defense in the body.
 - 3- **Specific immune response:** 3rd line of defense in the body.

I. Natural Barriers of the Body

- Study Doc.a, p.138.

1 Natural barriers of the body

The skin is virtually impermeable to foreign substances and micro-organisms.

Sweat is acidic ($\text{pH}=3.5$) and can destroy chemically micro-organisms that colonize the skin.

Non-pathogenic bacteria which live on the surface of the mucosa and are called "commensal flora", compete with harmful bacteria and make the internal medium unsuitable for their implantation.

Mucosal secretions, tears and saliva contain lysozyme, an enzyme that can destroy many bacteria.

Mucus in the nasal and bronchial secretions protects the respiratory tract by trapping inhaled particles and microbes. These are subsequently expelled from the body by the movement of the ciliated cells that line the mucosa.

The extreme acidity of the gastric juices ($\text{pH}=1-2$) destroys most ingested toxins and microbes chemically.

Vaginal secretions and semen contain anti-microbial substances.

Doc.a The natural barriers: first line of body defense.

I. Natural Barriers of the Body

- They prevent the entrance of foreign antigens into the body.
- They can be classified into:
 - Mechanical barriers: ex.skin.
 - Chemical barriers: ex. acidity in stomach and sweat.
 - Biological barriers:

Example: beneficial bacteria, non-pathogenic bacteria found in the small intestine.

II. Manifestations of a Non-specific Immune Response

- The non-specific immune response does not depend on the identity of the intruder. It attacks all the antigen in the same way.
- When there is a cut of the natural barriers, then the microbe will be able to cross this barrier and enter the body, where it will multiply and causes infection followed by inflammation.

- **During inflammation:**
 - Infected cells will release chemical molecules into the blood called **cytokines**.
 - Release of cytokines into the blood causes: redness, heat, and swell (edema).

- **Signs of inflammation:**

1. **Pain:** due to the stimulation of nerves (nociceptors).
2. **Redness:** due to dilation of blood capillaries.
3. **Heat:** due to the increase in blood flow.
4. **Edema:** due to leak out of plasma to the inflamed area from the capillary.

* Characteristics of Inflammatory Reaction:

- Rapid
- Local
- Non-specific

***Effector cells:** granulocytes and macrophages.

Phagocytosis

- Doc.b, p.139 shows the steps taking place during an inflammatory reaction:

1. Release of cytokines by infected cells.

2. Diapedesis: is the cross of monocytes and granulocytes of the capillary wall (blood vessel) and their migration into the inflamed tissue.

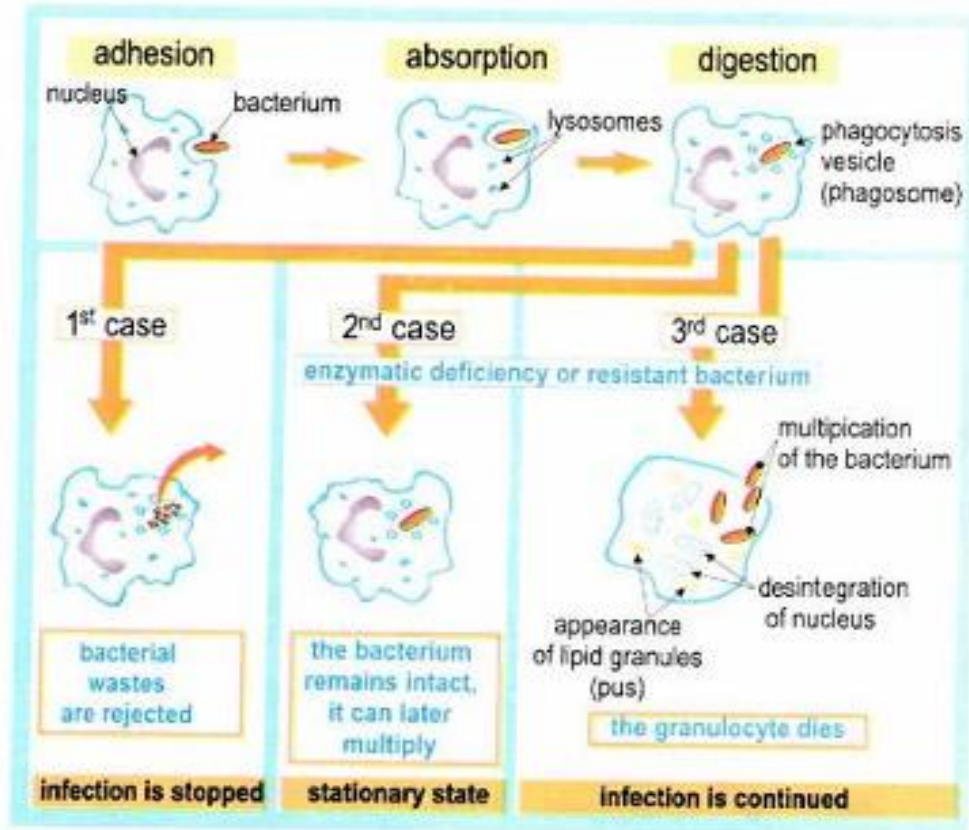

***Chemotactic process: is a process by which cells are attracted chemically.**
ex: cytokines attract phagocytes to the inflamed area.

3. **Phagocytosis:** is a non-specific immune response by which phagocytes (macrophages and granulocytes) eliminate the intruder.

* Steps of Phagocytosis: Doc.c, p.139.

- 1) Attraction, approaching and adhesion.
- 2) Absorption (engulfing).
- 3) Digestion and hydrolysis of the microbe: a phagocytosis vesicle containing the bacterium is formed called phagosome, where the digestion of the bacteria occurs by enzymes called lysosomes.

-phagosome = bacteria + lysosomes.

Doc.c The steps of phagocytosis: adhesion, absorption, digestion.

*Consequence of Phagocytosis: Doc.c (3 cases)

→ 1st case:

- Infection is stopped.
- The bacteria are digested by lysosomes and destroyed, where bacterial wastes are released.

Doc.c The steps of phagocytosis: adhesion, absorption, digestion.

*Consequence of Phagocytosis: Doc.c (3 cases)

→ 2nd case:

- Infection is in a stationary state.
- The bacteria remain intact and it is not destroyed by enzymes called lysosomes. It can multiply later.

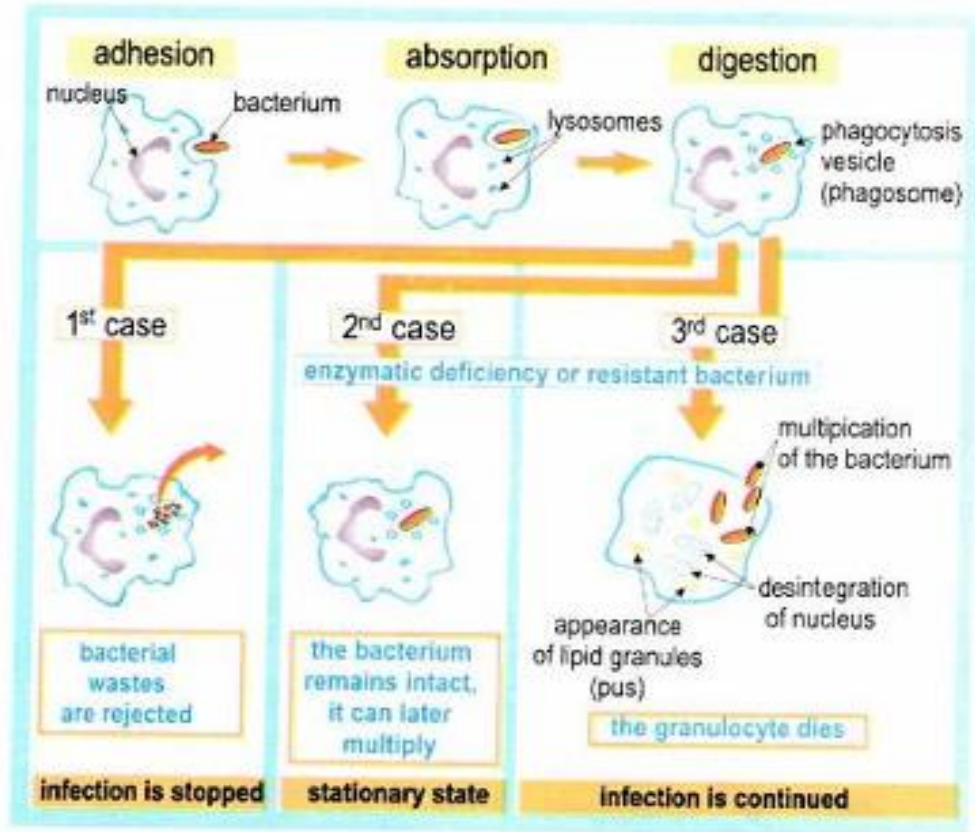

Doc.c The steps of phagocytosis: adhesion, absorption, digestion.

*Consequence of Phagocytosis: Doc.c (3 cases)

→ 3rd case:

- Infection is continued.
- The bacteria multiply inside the phagocyte and destroy it. So, the phagocyte dies and this result in pus (dead white blood cells).

✦ 2nd and 3rd cases may occur due to enzymatic deficiency in the lysosomes or due to resistant bacteria.

Doc.c The steps of phagocytosis: adhesion, absorption, digestion.

- Probing the Documents: p.139

Probing the documents

1. Define the natural barriers and classify them into mechanical and chemical barriers (*Doc.a*).
2. Observe the physiological events described in *doc.b*, and indicate which one causes each of the clinical signs of inflammation.
3. Describe the different steps of phagocytosis.
4. Why is phagocytosis referred to as a non-specific immune defense mechanism?
5. Formulate two hypotheses explaining how some foreign bodies may resist phagocytosis during the non-specific immune response.

5- Hypothesis 1: Foreign bodies are resistance or virulent.

Hypothesis 2: There is deficiency in lysosomes of phagocytes.
