

Physics – Grade 10

Unit 1: Electricity

Chapter 1: Electrostatic

Prepared and presented by: **Mr. Mohamad Seif**

OBJECTIVES

1 Definition of electrostatic

2 Structure of atom

3 Charge of a body

Definition of electrostatic

Electrostatics: is a branch of electricity concerned with static (stationary) charges which accumulate on the surface of the materials

Structure of atom

Matter is composed of atoms

- Each atom consists of a nucleus and electron cloud.
- The nucleus consists of two types of particles: **protons** which have a **positive** charge and **neutrons** which are **neutral**.
- The electrons are negatively charged and spread in the electron cloud around the nucleus.

Charge of a body

- The charge of an electron is $-e = -1.6 \times 10^{-19} \text{C}$ and the charge of a proton is $e = 1.6 \times 10^{-19} \text{C}$.
- In neutral bodies, the **number of electrons** in each atom is equal to the **number of protons**.
- If an object loses electrons, it has a deficit of electrons. So, it becomes positively charged object.
- If an object gains electrons, it has an excess number of electrons. So, it becomes negatively charged object.

Charge of a body

Total Charge (Q) of a body:

If an object has an excess or deficit of N electrons, its total charge is given by:

$$Q = N \times e$$

Where e is charge of one electron

Charge of a body

Application 1:

Consider a body containing 5.2×10^5 electrons. Calculate the total charge of the body.

$$|Q| = N \times e \rightarrow |Q| = (5.2 \times 10^5) \times (1.6 \times 10^{-19} \text{ C})$$

$$|Q| = 8.32 \times 10^{-14} \text{ C}$$

Law of electric charges

Unlike charges **attract** each other.

Like charges **repel** each other

OBJECTIVES

- 1 **Types of Electrifications**
- 2 **Electrification of friction**
- 3 **Electrification by contact**

Types of electrification

Electrification: is the process of charging objects by adding or removing electrons.

Electrification is of three types:

1. Electrification (Charging) by friction.
2. Electrification (Charging) by contact (conduction).
3. Electrification (Charging) by induction

Types of electrification

Electrification by friction:

If we rub an object (A) with another object (B), then:

Electrons transfer from one of them to the other:

The two bodies to become charged with **opposite charges**.

Types of electrification

If the electrons move from A to B, then:

Body (A) **loses electrons** (A has deficit of electrons) to become **positively charged**.

Body (B) **gains electrons** (B has excess in electrons) to become **negatively charged**.

At the end of electrification by friction the two bodies (A) and (B) **attract each other**, since they are of unlike charges

Types of electrification

Notes

During rubbing a piece of **glass** with a piece of **silk**, electrons transfer from the **glass** to **silk**

During rubbing a piece of **plastic** with a piece of **fur**, electrons transfer from the **fur** to **plastic**

Types of electrification

Application 2:

An ebonite rod (Kind of rubber) is rubbed with a piece of fur. Explain what happens ?

After rubbing, the ebonite rod with fur, some **electrons** moves from the **fur** to the ebonite rod, then:

The ebonite rod acquires an excess of electrons (negatively charged).

The fur acquires a deficit of electrons. (positively charged)

Types of electrification

Electrification by contact (Conduction):

When a negatively charged rod comes in contact with a neutral ball:
Some **electrons transfer** from the **rod** to the **neutral ball**.
The two bodies become of same sign (negatively charged)

The two bodies
repel each other
since they are of
like charges

Types of electrification

Conduction

Electrons transfer to the object
making it the same charge

Types of electrification

Application 3:

A positively charged glass rod in contact with the neutral ball
Explain what happens?

After contact, some electrons move from the neutral ball to the glass rod.

Types of electrification

For both the rod and the ball, the number of positive charges is greater than negative charges

Both are positively charged.

They repel each other, since they have same charge

OBJECTIVES

1 Electrification by Induction

2 Grounding

Types of electrification

Electrification by Induction:
No contact occurs between the two objects.

The charged object influences a neutral object.

A **Redistribution** of charges occur in the induced body

Positive Induction

Electrons Move Away
Side Becomes Positive

Types of electrification

Note:

An electroscope is used in different methods of electrifications.

The electroscope is an instrument used to detect the presence of electric charge on a body.

Types of electrification

Application 4:

A negatively charged rod is set close to a neutral ball of the electroscope).

Explain what happens?

The electrons of the negatively charged rod **repel** the electrons on the **neutral disc**

Redistribution of charges occurs on the electroscope.

Types of electrification

Some electrons move from the disc towards the leaves

The disc become positively charged, while the leaves become negatively charged.

The leaves then diverge.

If the rod is moved away, the electroscope returns neutral by redistribution of charges.

Types of electrification

Induction

Types of electrification

Application 5:

A positively charged rod is brought close to a neutral ball of the electroscope. Explain what happens?

The positive charges of the rod attract the electrons in the neutral disc & leaves. The electrons move from the leaves to disc.

Types of electrification

The negative charges arrange on the surface of the ball (Redistribution of charges).

The disc becomes negatively charged, while the leaves become positively charged

The leaves then diverge

If the rod is moved away, the electroscope returns neutral by redistribution of charges

Grounding

A charged object is grounded when it is connected to the earth through a connecting wire.

When a body is grounded, it return neutral body.

Grounding occurs by adding or removing electrons from the body.

Grounding

electrons flow from the earth to the metal ball to make it neutral.

electrons flow from the earth to the metal ball to make it neutral

Physics – Grade 10

Unit 1: Electricity

Chapter 1: Electrostatic

Prepared and presented by: **Mr. Mohamad Seif**

OBJECTIVES

1 Law of conservation of charges

2 Coulomb's law

Law of conservation of charges

Charge is never created or destroyed it is only transferred from one object to another.

The total number of charges of a body is conserved.

$$q_1 + q_2 = q'_1 + q'_2$$

Law of conservation of charges

Application 6:

Two identical charges A and B of charges $q_1 = -8 \times 10^{-6} \text{C}$ and $q_2 = 5 \times 10^{-6} \text{C}$ respectively.

The two charges are placed in contact then separated after a short time.

Calculate the charges of A and B after contact using law of conservation of charges

AB

Law of conservation of charges

$$q_1 = -8 \times 10^{-6} \text{ C}; q_2 = 5 \times 10^{-6} \text{ C}$$

Calculate the charges of A and B after contact the using law of conservation of charges

$$q_1 + q_2 = q'_1 + q'_2$$

But the two bodies are identical then: $q'_1 = q'_2$

$$q_1 + q_2 = q'_1 + q'_1 \Rightarrow q_1 + q_2 = q'_1 + q'_1 \Rightarrow q_1 + q_2 = 2q'_1$$

$$q'_1 = q'_2 = \frac{q_1 + q_2}{2} = \frac{-8 \times 10^{-6} + 5 \times 10^{-6}}{2} = -1.5 \times 10^{-6} \text{ C}$$

Coulomb's law

Statement of Coulomb's law:

The force of interaction between the two charges is proportional to the product of absolute values of the charges and inversely proportional to the square of the distance.

Be Smart
ACADEMY

$$F = \frac{K|q_1| \cdot |q_2|}{d^2}$$

Coulomb's law

Application 7:

Given: Two-point charges (A) and B of charges $q_1 = 2 \times 10^{-5} \text{ C}$ and $q_2 = -4 \times 10^{-5} \text{ C}$ respectively.

The two-point charges are separated by **30 cm**.

Given $K = 9 \times 10^9 \text{ S.I.}$

Calculate the attractive force between the two charges.

Coulomb's law

$$q_1 = 2 \times 10^{-5} \text{ C} ; q_2 = -4 \times 10^{-5} \text{ C} ; d = 0.3 \text{ m} ; K = 9 \times 10^9 \text{ S.I}$$

Calculate the attractive force between the two charges.

$$F = \frac{K|q_1| \cdot |q_2|}{d^2}$$

$$F = \frac{9 \times 10^9 |2 \times 10^{-5}| \cdot |-4 \times 10^{-5} \text{ C}|}{(0.3)^2}$$

$$F = 80 \text{ N}$$

The End
